Abstract—We present a well tested Python-based library for simulating and computing generalized fading channels, named yacoub. We describe the applicability of yacoub using examples in recent communications systems challenges, namely: cooperative spectrum sensing, bit error rate computation in generalized fading channel, and parameter estimation in free space optics. The development of yacoub open source and its code is available at http://github.com/mirca/yacoub.

## I. INTRODUCTION

### A. Note on notation

Scalars and random variables are denoted as *italic* small-case letters e.g. x; vectors and random vectors are denoted as italic, boldface, small-case letters e.g. x. The n-th component of a vector x is denoted as  $x_n$ . A complex vector of length n is defined as  $x \in \mathbb{C}^{n \times 1}$ . All vectors are column vectors. Matrices are denoted as italic, boldface, capital letters as in X; the identity matrix of order n is denoted as  $I_n$ . We define a discrete-time circularly symmetric Gaussian process z as any (finite or infinite) collection of random varibles z = x + jy,  $j \triangleq \sqrt{-1}$ , such that x and y are iid jointly Gaussian with zero mean vector and covariance matrix given by  $\mathbb{E}\left[zz^{\dagger}\right]$ , in which  $z^{\dagger}$  means the conjugate transpose of z and  $\mathbb{E}$  denotes the expected value. The probability of an event A is denoted as  $\mathbb{P}(A)$ .

### III. EXAMPLES

A. Spectrum Sensing in Complex Generalized Fading Channels

The spectrum sensing problem consists in deciding whether or not a given channel frequency band is being occupied by a licensed (primary) user and, in case that such frequency band is available, how to opportuniscally allocate secondary users such that the interference on the primary user is negligible.

From a probabilistic point of view, the spectrum sensing problem may be framed as a decision theory problem, as follows

$$H_0: \ \boldsymbol{y} = \boldsymbol{w},\tag{1}$$

$$H_1: \ \boldsymbol{y} = h\boldsymbol{s} + \boldsymbol{w},\tag{2}$$

in which  $\boldsymbol{y} \in \mathbb{C}^{n \times 1}$  is the decoded received vector signal,  $\boldsymbol{w} \in \mathbb{C}^{n \times 1}$  is complex Gaussian noise process with zero mean vector and covariance matrix given as  $\sigma^2 \boldsymbol{I}_n$ , and h is the channel gain.

In [?], the authors have shown that the probability distribution of the energy statistic  $\tilde{y} \triangleq y^{\dagger}y$  conditioned on the knowledge of h, in case that s is an M-PSK signal such that every symbol has the same probability of occurrence,  $\mathbb{P}(s_n = s) = \frac{1}{M}$ , is given as

$$p(\tilde{y}|h, H_1) = 1 - Q_n \left( \sqrt{\frac{2n|h|^2 E_s}{\sigma^2}}, \sqrt{\frac{2\tilde{y}}{\sigma^2}} \right), \quad (3)$$

in which  $Q_n$  is the Marcum-Q function and  $E_s$  is the energy per symbol.

The pdf of  $\tilde{y}$  can be written using the Law of Total Expectation

$$p(\tilde{y}|H_1) = \mathbb{E}\left[p(\tilde{y}|h, H_1)\right] = \int_{-\infty}^{+\infty} p(\tilde{y}|h, H_1)p(h) \, \mathrm{d}h. \quad (4)$$

Recall that the energy detection rule can be expressed as

$$d_{\delta}(\tilde{y}) = \begin{cases} 1, & \tilde{y} \ge \delta, \\ 0, & \tilde{y} < \delta, \end{cases}$$
 (5)

in which  $\delta$  is a strictly positive real number known as energy threshold, and  $d_{\delta}(\tilde{y}) = j, \ j \in \{0,1\}$  means that the detector has decided in favor of the hypothesis  $H_{j}$ .

As a result, the probabilities of false alarm and detection can be written as

$$p_f = 1 - p() \tag{6}$$

$$p_d = \tag{7}$$
